

Multi-column indexing: Takeaways

by Dataquest Labs, Inc. - All rights reserved © 2019

Syntax

- Creating a multi-column index:

```
CREATE INDEX index_name ON table_name(column_name_1, column_name_2);
```

Concepts

- When there are two possible indexes available, SQLite tries to estimate which index will result in better performance. However, SQLite is not good estimating and will often end up picking an index at random.
- Use a multi-column index when data satisfying multiple conditions, in multiple columns, is to be retrieved.
- When creating a multi-column index, the first column in the parentheses becomes the primary key for the index.
- A covering index contains all the information necessary to answer a query.
- Covering indexes don't apply just to multi-column indexes.
